Why bit twiddling?

- When setting PORTs and DDRs, one needs to be careful not to disturb the state of other bits of the register.
- For example, the following code attempts to set pin 2 of PORTD

```
DDRD |= 0b00000100;
```

- Unfortunately, this code also clears all other bits of PORTD
- Bit twiddling allows not to set all 8 bits in register PORT without regard for the directions of each individual pin, i.e. all the bits stored in DDR
- For example, the above example could be best solved as follows

```
DDRD = DDRD | (1<<2);
/*which can also be written as*/
DDRD |= (1<<2);</pre>
```

■ Please read "Programming 101 - By Eric Weddington"⁵ for more details.

- Bit shifting—a bitwise operator that allows to move (to the left or right) the order of one or several bits.
- Bit-shifting is very fast and required fewer CPU operations compared to arithmetic (e.g., multiplication and division) operations.
- Bit shifting uses Bitwise Operators⁶

Operator	Name	Example	Result
&	Bitwise AND	6 & 3	2
1	Bitwise OR	10 10	10
↑ TechVidvan	Bitwise XOR	2^2	0
~	Bitwise 1's complement	~9	-10 Tech Vidyan
<<	Left-Shift	10<<2	40
>>	Right-Shift	10>>2	2

FIG 1. Example of Bitwise operations

There are three main types of shifts:

- Left Shifts—When shifting left, the most-significant bit is lost, and a 0 bit is inserted on the other end.
 - The left shift operator is usually written as <<</p>

```
(0010 << 1) = 0100   /* (2 << 1) = 4*/   (0010 << 2) = 1000   /* (2 << 2) = 8*/
```

There are three main types of shifts:

- Left Shifts—When shifting left, the most-significant bit is lost, and a 0 bit is inserted on the other end.
 - The left shift operator is usually written as <<</p>

```
(0010 << 1) = 0100  /* (2 << 1) = 4*/  (0010 << 2) = 1000  /* (2 << 2) = 8*/
```

- Right Shifts—When shifting right with an arithmetic right shift, the least-significant bit is lost and the most-significant bit is copied.
 - The right shift operator is usually written as >>

```
(1011 >> 1)=1101   /*(11>>1)=5 */

(1011 >> 3)=0001   /*(11>>3)=1 */
```

There are three main types of shifts:

- Left Shifts—When shifting left, the most-significant bit is lost, and a 0 bit is inserted on the other end.
 - The left shift operator is usually written as <<</p>

```
(0010 << 1) = 0100   /*(2 << 1) = 4*/   (0010 << 2) = 1000   /*(2 << 2) = 8*/
```

- Right Shifts—When shifting right with an arithmetic right shift, the least-significant bit is lost and the most-significant bit is copied.
 - The right shift operator is usually written as >>

■ Logical Right Shifts—When shifting right with a logical right shift, the least-significant bit is lost and a 00 is inserted on the other end.

```
(1011 >>> 1) = 0101
(1011 >>> 3) = 0001
```

Controlling Memory-Mapped I/O

Registers Using Bit Operations

Setting Bits with the OR operator

Consider the diodes in Figure 4 and Figure 5⁷

How would you turn on LED1 while other LEDs are turned off?

```
/*set the pin as an output*/
DDRB |= (1<<PBO);
/*set the bit PBO as high*/
PORTB |=(1<<PBO);</pre>
```

■ How would you turn on only LED2 and LED3 and leave out other LEDs in their previous state?

```
PORTB &= ~((1<< PB1) | (1<< PB2));
```

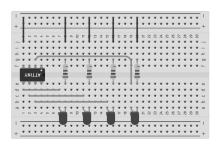

FIG 2

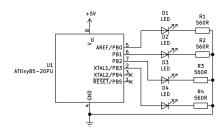

FIG 3

Clearing a bit with AND and NOT operators

■ How to turn OFF LED 1 only

```
/*Set PBO to low*/
PORTB &=~(1<<PBO);</pre>
```

■ How would you turn OFF only LED2 and LED3 and leave out other LEDs in their previous state?

```
PORTB &=~(1<<PB1) | (1<<PB2);
```

NOTE: There is a NOT outside the parentheses in order to have two zeros

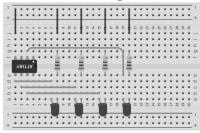

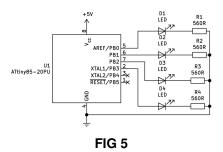

FIG 4

Toggling Bits with XOR operator

How to toggle OFF LED 1 only

```
PORTB ^= (1<<PBO);
```

■ How to toggle only LED2 and LED3 and leave out other LEDs in their previous state?

```
PORTB ^=((1<<PB1)|(1<<PB2));
```

Noted:

- Don't forget to set direction of pins first! else, the pin will not be set
- Remember if pins are configured as inputs (DDRBn bit is 0) then the corresponding bit in PORTBn sets the pull-up status

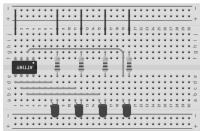

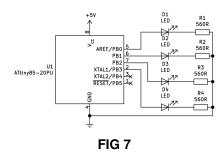

FIG 6

Testing a Bit

- Suppose we need to know if the switch S1 is pressed
- We use the PIN register to know the content of the PORT

```
int status=(PINB & (1<<PB));
if(status) {
    // If the switch is pressed
}</pre>
```

■ You can also check multiple switches

```
int status=PINB &((1<<PB4) |
     (1<<PB5));
if(status) {
// If any of the switches is
     pressed</pre>
```

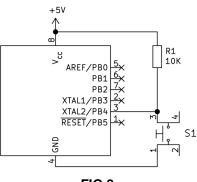

FIG8

AVR bit twiddling

TAB 1. Important bit-twiddling operations.

Operation	Implementation in C	Implication
Set a bit	PORTB = (1< <pb1)< td=""><td>Bit PB1 is set to 1 (other pins are left unchanged)</td></pb1)<>	Bit PB1 is set to 1 (other pins are left unchanged)
Clear bit	PORTB &= ~(1< <pb1)< td=""><td>Bit PB1 is set to 0 (other pins are left unchanged)</td></pb1)<>	Bit PB1 is set to 0 (other pins are left unchanged)
Toggle a bit	PORTB ^= (1< <pb1)< td=""><td>If Bit PB1 was 1, it is toggled to 0. Otherwise, it is set to 1 (other pins are left unchanged)</td></pb1)<>	If Bit PB1 was 1, it is toggled to 0. Otherwise, it is set to 1 (other pins are left unchanged)
Read a value bit	<pre>uint8_t bit = PORTB & (1<< PB1)</pre>	Read and put the value of bit PB1 of PORTB into the variable bit. This is used to read switches.

Important readings:

- Please read the document—which is uploaded on the course website—entitled 'AVR Bit Twiddling' to better understand this important topic.
- You should also read "Bit manipulation" by By Eric Weddington 8

Special bit twiddling AVR functions

One can use the $_{BV(x)}$ macro defined in avr/sfr _defs.h which is included through avr/io.h as #define _BV(x) (1 «x)

```
DDRD &= \sim_BV(0); //set PORTD pin0 to zero as
    input
PORTD = BV(0); //Enable pull up;
DDRD \mid = \_BV(1); //set PORTD pin1 to one as output
PORTD |= _BV(1); //led ON
while (1) {
  if (bit_is_clear(PIND, 0)) {
   //if button is pressed
   while (1) {
      PORTD &= ~_BV(1); //turn the led OFF
      //LED OFF while Button is pressed
      loop_until_bit_is_set(PIND, 0);
      PORTD \mid = \_BV(1); //turn the led ON
```

Software Delay Functions

AVR GCC compiler's util/delay.h defines the _delay_ms(double ms) function

- Requires # include <util/delay.h >
- F_CPU preprocessor symbol should be defined as MCPU frequency in Hz using #define or passed through the -D compiler option
 - In code: #define F_CPU 8000000UL //8 MHz clock
 - Command line option: -D F_CPU=8000000UL
- The maximum delay is calculated as

$$delay = \frac{4294967.295 \cdot 10^6}{F_CPU} \tag{1}$$

■ Thus, for an 8MHz clock, the maximum delay would be

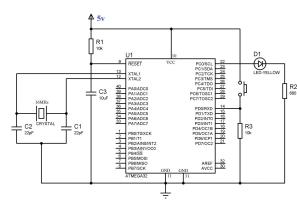

$$delay = \frac{4294967.295 \cdot 10^6}{8 \cdot 10^6} = 536871 ms \tag{2}$$

Example: blink an LED

```
#define F CPU 8000000UL
                                                                 5V
#include <avr/io.h>
#include <util/delav.h>
int main(void)
    //Set all pins of DDR3 as output
    DDRD = DDRD | (1 << 3);
   while(1)
                                                   LED
        //Turn on the LED by making pin PD3 high
        PORTD = PORTD | (1 << 3);
        // Wait one second
        delay ms(1000);
                                                                                     ATmega16
                                                                  470Ω
        // Turn of the LED by making pin PD3 low
        PORTD = PORTD & (\sim(1<<3));
                                                                                 PD3
        delay ms(1000);
        return 0;
                                                                                 GND
```

Example: Reading switch

```
#include <avr/io.h>
#include <util/delay.h>
int main(void) {
  //Set PCO as Output
  DDRC \mid = (1 \ll PC0);
  //Set PDO as an input
  DDRD &= \sim(1 << PD0);
  while (1) {
    //Turns OFF LED
    PORTC \&= \sim (1 \ll PC0);
    //If switch is pressed
    if (PIND & (1 << PD0) == 1) {
      //Turns ON LED for one second
      PORTC \mid = (1 \ll PC0);
      _{delav_{ms}(1000)}:
```

The end
